Keywords: antagonist, CXCR4, cyclopentapeptide, peptidomimetic, scaffold

ABSTRACT

Structure-activity relationship studies of the cyclopentapeptide CXCR4 antagonists (cyclo(-L-/D-Arg¹-Arg²-2-Nal³-Gly⁴-D-Tyr⁵-)) suggest that the L-/D-Arg¹-Arg²-2-Nal³ tripeptide sequence contained within these cyclopentapeptides serves as a recognition motif for peptidic CXCR4 antagonists. Starting by dissecting the cyclopentapeptide structure and reintroducing cyclic constraints in a stepwise manner, we here report a novel class of scaffold-based tripeptidomimetic CXCR4 antagonists based on the D-Arg-Arg-2-Nal motif. Biological testing of the prototype compounds showed that they represent new peptidomimetic hits; importantly, the modular nature of the scaffold provides an excellent starting point for future ligand development.

INTRODUCTION

CXC chemokine receptor 4 (CXCR4) is a peptidergic GPCR with the 68-residue peptide CXC chemokine ligand 12 (CXCL12) as its only endogenous ligand.^{1, 2} In addition to the developmental and physiological role of CXCL12/CXCR4, CXCR4 has been shown to be involved in a number of pathological conditions, including HIV, cancer, and rheumatoid arthritis.³ Consequently, CXCR4 has emerged as an attractive drug target, and several small-molecule CXCR4 antagonists have been described in the literature over the last decade,^{3, 4} including a series of cyclic pentapeptides based on the amino acid sequence L-/D-Arg¹-Arg²-2-Nal³-Gly⁴-D-Tyr⁵ (2-Nal = L-3-(2-naphthyl)alanine), i.e. the L-Arg¹ epimer **1** (FC131) and the D-Arg¹ epimer **2** (FC092) (Figure 1).⁵

Figure 1. Structures of the lead cyclopentapeptide antagonists **1** and **2**.

Small cyclic peptides, such as cyclopentapeptides, are known to mimic peptide turns,⁶ i.e. structural motifs where the peptide backbone folds back on itself to form a pseudo-cyclic structure. Such turns appear to be a universal ligand recognition element for peptidergic GPCRs;⁷ thus, the cyclopentapeptide CXCR4 antagonists represent an excellent starting point for design of novel CXCR4 antagonists based on smaller turn-mimicking scaffolds. Such scaffolds have to maintain the 3D-orientation of the pharmacophoric groups of the parent peptide, resulting in a so-called topographical (or type-III) peptidomimetic.⁸ Interestingly, a recent review of the biological importance of tripeptide motifs indicates that three amino acids represent an optimal size for small-molecule peptidomimetics.⁹

The Gly⁴ residue in the cyclopentapeptide CXCR4 antagonists (Figure 1) was originally introduced for synthetic reasons⁵ and can be considered as a spacer. Further, SAR studies of **1** and **2** have shown that partial biological activity is retained in the absence of the neighboring D-Tyr⁵ side chain,^{10, 11} and based on molecular docking we have recently suggested that this is due to lack of a defined binding pocket for the D-Tyr⁵ side chain, which results in partial solvent exposure of the phenyl ring.¹¹ Collectively, these observations imply that the remaining L-/D-Arg¹-Arg²-2-Nal³ tripeptide fragment serves as a recognition motif for peptidic CXCR4 antagonists, and motivate further studies of both flexible and constrained small molecules

12 13 14 15 **RESULTS AND DISCUSSION**

16
17 **General Design Considerations.** As SAR studies of the cyclopentapeptide CXCR4
18 antagonists (Figure 1) have demonstrated that position 2 (L-Arg) is very sensitive to structural
19 modifications,^{12, 13} we decided to keep L-Arg² throughout this study. Similarly, we have recently
20 shown that replacement of L-2-Nal in position 3 with aromatic/alicyclic analogs results in
21 significant reduction of the antagonistic potency,¹¹ and therefore used a 2-naphthyl group with
22 the appropriate spacer length for all compounds. In contrast, position 1 has been shown to be
23 relatively tolerant to structural modifications, both with respect to stereochemistry (L- or D-
24 arginine) and the chemical nature of the side chain.^{13, 14} Even if the originally discovered L-Arg¹
25 epimer **1** displays somewhat higher activity than the D-Arg¹ epimer **2** (Figure 1; IC₅₀-values of
26 0.004 and 0.008 μM, respectively),⁵ subsequent SAR studies have shown that cyclopentapeptide
27 analogs containing D-Arg¹ in many cases are more active than the corresponding L-Arg¹ epimers.
28 For example, the most active cyclopentapeptide CXCR4 antagonist reported to date is the *N*-
29 methylated D-Arg¹ epimer FC122 (cyclo(-*N*-Me-D-Arg¹-Arg²-2-Nal³-Gly⁴-D-Tyr⁵-)), which
30 showed 8-fold higher affinity than the corresponding L-Arg¹ epimer (IC₅₀-values of 0.003 and
31 0.023 μM, respectively).¹⁰ Moreover, head-to-tail cyclization of peptides is known to be
32 facilitated by incorporation of a D-amino acid in an all-L sequence due to a turn-inducing
33 effect.¹⁵ For these reasons, we decided to focus on the D-Arg¹ epimers in the present study, using

the lead cyclopentapeptide **2** (cyclo(-D-Arg¹-Arg²-2-Nal³-Gly⁴-D-Tyr⁵-), Figure 2A) as starting point.

Biological Evaluation. The antagonistic potency of the synthesized compounds **2–14** (Figures 2 and 6) on human CXCR4 was determined by a functional assay as previously described¹³ and is shown in Table 1; the EC₅₀-value of the known lead compound **2** was 0.52 μM.

Figure 2. Structures of (A) the lead cyclopentapeptide **2**, (B) the tripeptidic compounds **3–4**, and (C) the macrocyclic compounds **5–10**.

Design and SAR. *Linear Tripeptidic Compounds.* Taking a minimalist approach, **2** was initially dissected to the linear peptidic derivative **3** (Figure 2B) in order to determine the activity of the isolated Arg¹-Arg²-2-Nal³ motif. The *N*-acetylated D-Arg¹-Arg²-2-Nal³ tripeptide amide **4** (Figure 2B) was also included to study the role of the two flanking amide groups. Compound **3** (EC₅₀ = 58 μM) displayed 112-fold lower potency than **2**, reflecting the extensive dissection of the cyclopentapeptide structure. This finding is consistent with literature data for similar linear

tripeptidic CXCR4 antagonists originating from an Arg-Arg-Nal motif;^{16, 17} representative structures are shown in Figure 3. In the same way as **3**, these compounds were based on a central L-arginine, and were found to have moderate potency (anti-HIV assay), typically in the order of 100-fold reduction relative to the parent cyclopentapeptide.

Figure 3. Structures of previously reported linear tripeptidic CXCR4 antagonists.^{16, 17}

Interestingly, the N- and C-terminal capped linear tripeptide **4** showed lower activity ($EC_{50} = 86 \mu\text{M}$) than **3**; thus, the terminal amide groups of **4** do not contribute favorably to activity. The activity of **4** relative to **2** (165-fold reduction) is consistent with SAR studies by Fujii *et al.*, which showed that the linear N- and C-terminal capped pentapeptide Ac-D-Arg¹-L-Arg²-L-2-Nal³-Gly⁴-D-Tyr⁵-NH₂ was 173-fold less potent (anti-HIV assay) than the parent cyclopentapeptide **2**.⁵

Macrocyclic Compounds. The analogs **3** and **4** are quite flexible, which is generally considered as an undesirable feature, and a macrocyclic constraint was reintroduced to force the D-Arg¹-Arg²-2-Nal³ motif into a more restricted conformation (Figure 2C). Use of a Gly⁴-Gly⁵ dipeptide

1
2
3 spacer to give a simplified cyclopentapeptide (**5**) resulted in 2-fold increase in potency ($EC_{50} =$
4 $44 \mu\text{M}$) relative to **4**. Simplification of **5** by replacement of Gly⁴-Gly⁵ with the flexible 5-
5 aminopentanoic acid⁴ hydrocarbon spacer (**6**) resulted in loss of activity in our assay ($EC_{50} > 100$
6 μM). This shows that the Gly⁴-Gly⁵ amide bond in **5** contributes favorably to activity, either by a
7 geometrical effect or through direct binding interactions.
8
9

10
11
12
13
14
15 Next, we employed a ring expansion/contraction strategy by using ω -amino carboxylic acid
16 spacers of different length (**7–10**, Figure 2C). Extension of the hydrocarbon spacer in **6** (15-
17 membered ring) to give a 16-membered ring (**7**) or contraction to give a 14-membered ring (**8**)
18 still did not give any measurable activity ($EC_{50} > 100 \mu\text{M}$ for both compounds). Similarly, the
19 13-membered ring (**9**) was inactive ($EC_{50} > 100 \mu\text{M}$); however, the further constrained
20 cyclotetrapeptide **10** (12-membered ring) was equipotent ($EC_{50} = 60 \mu\text{M}$) with the linear
21 tripeptidic compound **3**.

30

31
32 *Bicyclic Tripeptidomimetics.* Encouraged by the activity of **10**, we set out to develop a further
33 constrained turn-mimicking scaffold capable of presenting the side chains and backbone of the
34 D-Arg¹-Arg²-2-Nal³ fragment of the cyclopentapeptide **2** in the required 3D-orientation. The key
35 to successful development of such topographical peptidomimetics is knowledge of the bioactive
36 conformation of the parent peptide, in this case the cyclopentapeptide ligands. Based on an
37 extensive exploration of the conformational space for a series of cyclopentapeptide CXCR4
38 antagonists from the literature, we have previously reported a 3D pharmacophore model that
39 describes the spatial arrangement of the pharmacophoric side chains as well as the bioactive
40 conformation of the cyclopentapeptide backbone.¹⁸

50
51

52
53 Searching through the extensive literature on turn-mimetics (see ref¹⁹ for a review), we were
54 intrigued by the tripeptide-derived 3,6,8-trisubstituted²⁰ bicyclic structure **A** (Figure 4A),^{21, 22}
55
56
57
58
59
60

1
2
3 which contains two endocyclic amide bonds. The synthesis of **A** was first reported by Vojkovsky
4
5 *et al.* who suggested it as a potential peptide–turn motif,²¹ however, no biological applications of
6
7 **A** have yet been reported. In order to elucidate whether this scaffold would be suitable for our
8
9 purpose, a structural comparison of low-energy conformations of **A** with our 3D pharmacophore
10
11 model was undertaken. This showed that scaffold **A** is able to orient the side chains in a similar
12
13 way as the parent cyclopentapeptide (Figure 4B).
14
15
16
17

2
3 **Figure 5.** (A) Structures of the diastereomeric scaffolds **A** and **A'**, and (B) superimposition of
4 low-energy conformations of **A** (grey carbon atoms) and **A'** (green carbon atoms).
5
6
7

8
9 Scaffold **A** contains three stereocenters, where two (C3 and C6) are defined by the building
10 blocks (see Scheme 4 in Chemistry section). The bridge-head stereocenter (C9a) is formed in the
11 final cyclization step, and the stereochemical outcome has been shown to be governed by the
12 configuration at C3 (see Chemistry section);²³ thus, two diastereomeric scaffolds **A** and **A'**
13 (Figure 5A) can be prepared. Interestingly, structural comparison of the expected bioactive
14 conformation of **A** (shown in Figure 4B) with low-energy conformations of **A'**, showed that **A'**
15 can adopt an almost identical conformation with respect to the orientation of the two amide
16 bonds and the three side chains (Figure 5B).
17
18
19
20
21
22
23
24
25
26

27
28 Thus, we decided to pursue tripeptidomimetic CXCR4 antagonists **11** and **12** (Figure 6), that
29 are based on bicycles **A** and **A'** respectively, where L- and D-cysteine have been used as building
30 blocks, to give an amide in the R¹ side chain. In order to introduce the same arginine R¹ side
31 chain as the parent cyclopentapeptide, we also adapted the synthesis to allow for preparation of
32 **13** and **14** (Figure 6). Interestingly, compounds **11** and **12** were inactive, while compounds **13**
33 and **14** (EC₅₀ = 80 and 64 μM, respectively) showed activity similar to **3** and **10**. Clearly, the
34 amide bond in the R¹ side-chain of **11** and **12** is unfavorable for the biological activity, an
35 observation that justifies the synthetic effort put into the R¹ building block **33** that was used for
36 **13** and **14** (see Scheme 7, Chemistry section).

59
60

Figure 6. Structures of the bicyclic target compounds **11–14**.

Obviously, the scaffold-based tripeptidomimetics **13** and **14** are significantly less potent (154- and 123-fold, respectively) than the optimized cyclopentapeptide **2** that they are based on; however, this was an expected consequence of the rather extensive structural changes that were needed in order to arrive at downsized structures. To our knowledge, there are only two other examples of scaffold-based tripeptidomimetic CXCR4 antagonists in the literature (Figure 7): Niida *et al.* used a 1,3,6-trisubstituted 1,6-dihydropyridin-2-one scaffold,²⁴ while Ueda *et al.* have reported a series of achiral CXCR4 antagonists based on a 1,2,5-trisubstituted indole scaffold.²⁵ Also for these compounds, a significant drop in activity compared to the parent cyclopentapeptides was observed; the same group has typically reported an IC_{50} -value of 0.008 μ M for the cyclopentapeptide **2**, which means that the affinity reduction for the dihydropyridin-2-one based compound ($IC_{50} = 15.1 \mu$ M) and the indole-based compound ($IC_{50} = 3.0 \mu$ M) was 1888- and 375-fold, respectively. These numbers reflect the general complexity of the initial “scaffold jump” for prototype compounds, as also seen in the present study.

1
2
3 The moderate activity of the prototype bicyclic tripeptidomimetics also means that binding
4 mode studies (typically performed by combining site-directed mutagenesis studies and molecular
5 docking) are not expected to provide reliable data. Thus, further SAR studies, aimed at
6 optimizing both the scaffold core and the side chains, are currently in progress, and the results
7 will be reported in due course.

38

39 **Chemistry.** The macrocyclic compounds **2** and **5–10** were prepared by head-to-tail
40 macrolactamization of linear precursors (Scheme 1) that were obtained through Fmoc-based
41 solid phase peptide synthesis (SPPS). The linear precursors were prepared using either a
42 preloaded Fmoc-Gly trityl resin (**2**, **5**, and **10**) or a 2-chlorotrityl chloride resin for the loading of
43 the N-Fmoc ω-aminocarboxylic acids (**6–9**). Cleavage from the resin was facilitated using
44 hexafluoroisopropanol (HFIP) and the side-chain protected peptides were cyclized using PyBOP
45 followed by global deprotection using TFA.

Scheme 1. Synthesis of **2** and **5–10**.

Reagents and conditions: (a) *N*-Fmoc ω-aminocarboxylic acid, DIPEA, CH₂Cl₂; (b) MeOH, DIPEA, CH₂Cl₂; (c) HFIP, CH₂Cl₂; (d) PyBOP, DIPEA, DMF/CH₂Cl₂; (e) TFA/TIS/H₂O.

Compound **3** was synthesized (Scheme 2) by coupling protected arginine **15** with 2-(naphthalene-2-yl)ethan-1-amine to give **16**, which in turn was Fmoc-deprotected and coupled with *N*-Boc 5-aminopentanoic acid to give **17**. Global deprotection facilitated by TFA followed by guanidinylation of the primary amine gave **3**.

Scheme 2. Synthesis of **3**.

Reagents and conditions: (a) 2-(Naphthalene-2-yl)ethan-1-amine hydrochloride, HBTU, DIPEA, DMF (67%); (b) 2-ethanolamine, DMF; (c) *N*-Boc 5-aminopentanoic acid, HATU, DIPEA, DMF; (d) TFA/TIS/H₂O; (e) 1*H*-pyrazole-1-carboxamide hydrochloride, DIPEA, DMF (21% over four steps).

The linear tripeptide **4** was prepared by Fmoc-based SPPS on an Fmoc-NH-Rink amide resin (Scheme 3) followed by acetylation of the N-terminal using acetic anhydride. Cleavage from the resin and global deprotection mediated by TFA gave the desired N-acetylated tripeptide amide **4**.

Scheme 3. Synthesis of **4**.

Reagents and conditions: (a) Ac_2O , DIPEA, DMF; (b) TFA/TIS/ H_2O .

The key step in the synthesis of the bicyclic tripeptidomimetics **11–14** (Scheme 4) is the spontaneous formation of the 6,6-fused bicyclic ring system **A** upon treatment of acetal **C** with TFA.^{21, 22} The resulting aldehyde condensates with the backbone amide nitrogen to give the *N*-acyliminium ion intermediate **B**, which subsequently undergoes nucleophilic attack from the deprotected thiol, resulting in the formation of the desired bicycle **A**.^{21, 22} The cyclization occurs stereoselectively,²³ and the configuration at the bridge-head (C9a) is dependent on the configuration at C3 (R^1 substituent), and in the absence of a R^1 substituent on the configuration at C6.

Scheme 4. Scaffold and retrosynthetic strategy.

Synthesis of the linear precursor **C** requires access to the three building blocks **D**, **E** and **F**. For the synthesis of target compounds **11** and **12** (Figure 6), the R¹-side chain (incorporated through building block **F**) was introduced as guanidinylated glycine **20** (Scheme 5). This material was prepared by guanidinylation of glycine methyl ester hydrochloride (**18**) using *N,N*-di-Boc-1*H*-pyrazole-1-carboxamide followed by hydrolysis of the methyl ester of the resulting **19** using LiOH in a mixture of water and acetone.^{26, 27}

Scheme 5. Synthesis of carboxylic acid **20**.

Reagents and conditions: (a) *N,N*-di-Boc-1*H*-pyrazole-1-carboxamide, DIPEA, DMF (85%); (b) LiOH, H₂O/acetone (99%).

Synthesis of the bicyclic core (Scheme 6) commenced with the alkylation of 2-(naphthalene-2-yl)ethan-1-amine (**21**) with bromoacetaldehyde dimethyl acetal in refluxing THF to give secondary amine **22**. This amine was in turn coupled with protected arginine (**15**) to give **23** in high yield. Further Fmoc-deprotection and coupling with appropriately protected L-cysteine gave **24**, which was submitted to another Fmoc-deprotection and then coupled with carboxylic acid **20** to give the linear precursor **25**. This material was treated with TFA, thioanisole and water to facilitate global deprotection, leading to formation of the acyliminium ion intermediate that after nucleophilic attack by the thiol gave **11**. The diastereomeric **12** was prepared by coupling of Fmoc-D-Cys(Trt)-OH to Fmoc-deprotected **23** to give intermediate **26** (see Experimental section), which in turn was converted to linear precursor **27** followed by deprotection and cyclization to give **12**.

Scheme 6. Synthesis of the bicyclic tripeptidomimetic **11**.

Reagents and conditions: (a) $\text{BrCH}_2\text{CH}(\text{OMe})_2$, THF, reflux (30%); (b) Fmoc-Arg(Pbf)-OH (**15**), HATU, DIPEA, DMF (83%); (c) Et_2HN , CH_2Cl_2 ; (d) Fmoc-L-Cys(Trt)-OH, HATU, DIPEA, CH_2Cl_2 (49% over two steps); (e) Et_2HN , CH_2Cl_2 ; (f) **20**, HATU, DIPEA, CH_2Cl_2 (57% over two steps); (g) TFA/thianisole/ H_2O .

The configuration of the newly formed stereocenters at the bridge-head carbon atoms (C9a) in **11** and **12** (see Figure 5) was determined using the 2D ^1H ROESY experiment (see Supporting Information for detailed ROESY spectra and NMR signal assignment for **11** and **12**). The known configurations of C6 (*S* for both **11** and **12**) and C3 (*R* for **11** and *S* for **12**) were used as prerequisites for determination of the configuration of C9a. The strong cross-peaks observed at δ 5.09/4.71 (H9a/H3), δ 5.09/1.73 (H9a/H β arginine R 2) and the medium strong cross-peak at δ 5.09/1.44 (H9a/H γ arginine R 2) observed in the 2D ROESY spectrum of **11** confirmed the (*S*) configuration of C9a in **11**. Moreover, the strong cross-peak observed at δ 5.00/4.72 (H9a/H3) in the 2D ROESY spectrum of **12** and the presence of only very weak cross-peaks at δ 5.00/1.64

(H9a/Hβa arginine R²) and δ 5.00/1.52 (H9a/Hβb arginine R²) confirmed the (*R*) configuration of C9a in **12**.

The **F** building block required for target compounds **13** and **14** required a multi-step synthesis (Scheme 7). 2-Oxopiperidine derivative **28** was selectively reduced using freshly prepared Ca(BH₄)₂, and after an acidic work-up, alcohol **29** was isolated in good yield.²⁸ The alcohol was next taken through a carbodiimide-mediated dehydration to give α,β-unsaturated lactam **30**.²⁸ Use of *N*-(3-dimethylaminopropyl)-*N'*-ethylcarbodiimide (EDC) in refluxing toluene gave up to 73% yield, while DCC gave the product in quantitative yield. In both cases, CuI was added to activate the carbodiimide. Next, the lactam was Boc-protected to give **31** followed by Michael addition of triphenylmethane thiol to give racemic **32**, with excellent yield in both steps. Finally, the Boc-protected lactam was hydrolyzed using LiOH to give racemic carboxylic acid **33** in high yield.

Scheme 7. Synthesis of building block **33**.

Reagents and conditions. (a) CaCl₂, NaBH₄, MeOH, 0 °C to r.t. (76%); (b) DCC, CuI, toluene, 110 °C (quant); (c) Boc₂O, Et₃N, DMAP, CH₂Cl₂/DMF (94%); (d) Ph₃CSH, Et₃N, CH₂Cl₂ (95%); (e) 1M aq. LiOH, THF (94%).

Assembly of the linear precursors for target compounds **13** and **14** (Scheme 8) was carried out by Fmoc-deprotecting **23** and subsequent coupling of the resulting material with carboxylic acid **33**, to give **34** as an inseparable mixture of diastereoisomers. Linear precursor **34** was globally deprotected and cyclized, and the amino group was guanidinylated to give **13** and **14**.

Scheme 8. Synthesis of **13** and **14**.

Reagents and conditions. (a) Et_2HN , CH_2Cl_2 ; (b) **33**, HBTU, DIPEA, CH_2Cl_2 (85% over two steps); (c) TFA/thioanisole/ H_2O ; (d) 1*H*-pyrazole-1-carboxamide hydrochloride, DIPEA, DMF.

RP-HPLC analysis after guanidinylation showed two distinct peaks, which were separable by semi-prep RP-HPLC. NMR analysis of the two isolated products clearly showed that they each were single diastereoisomers. Thus, only two out of four possible products were formed in the cyclization of the diastereoisomers of **34**. For the two isolated products, only the configuration at C6 (*S*) was known, and the configuration of C3 and C9a was determined using the 2D ^1H ROESY experiment. For both **13** and **14**, strong cross-peaks between H9a and H3 (at δ 5.14/2.74 and at δ 4.66/2.38 for **13** and **14**, respectively) were observed, indicating similar overall geometry to that of **11** and **12**. The presence of a cross-peak between H9a and H γ arginine R² was observed only in the ROESY spectrum of **13** suggesting that the configuration of C9a for this compound is *S*, whereas the configuration of C9a for the stereoisomer **14** is *R*. Since H9a

1
2
3 and H3 are *cis* in both **13** and **14**, the configuration at C3, which stems from the racemic
4
5 carboxylic acid **33**, is *R* in **13** and *S* in **14**. It is interesting to note that *S* configuration of C9a in
6
7 **11** and **13** leads to a downfield shift of H6 when compared with the analogous *R* isomer. Grimes
8
9 *et al.* speculated that a solvent mediated hydrogen bond between the R¹-side chain amide NH and
10
11 the ring carbonyl group could contribute to stabilizing a conformation in which the R¹ substituent
12
13 is in an equatorial position, which favors the observed stereoselectivity of the cyclization.²³
14
15 However, for the formation of **13** and **14**, the absence of a R¹ amide NH did not influence on the
16
17 stereoselectivity in the cyclization step.

24 CONCLUSIONS

25
26
27 In this work we have demonstrated that new scaffold-based tripeptidomimetic CXCR4
28
29 antagonists can be rationally designed from cyclopentapeptide CXCR4 antagonists. The bicyclic
30
31 compounds reported herein represent an interesting class of new tripeptidomimetic CXCR4
32
33 antagonists, and although the prototype compounds showed moderate activity, they serve as
34
35 useful leads for further optimization. The peptidomimetic scaffold we have employed is
36
37 constructed from three building blocks, each containing one of the pharmacophoric groups, and
38
39 therefore allows for synthetic access to a range of target molecules. We envision that further
40
41 SAR studies involving the three different binding groups will afford new and optimized CXCR4
42
43 antagonists.

EXPERIMENTAL SECTION

Chemistry. General. All reagents and starting materials were purchased from Sigma-Aldrich and used as delivered unless otherwise stated. Cyclic peptide **2** was prepared as previously described.¹³ Anhydrous toluene, CH₂Cl₂ and THF were obtained from an anhydrous solvent delivery system (SDS-800 from mBraun) at the Department of Chemistry, University of Bergen. Analyses using thin layer chromatography were performed on Alugram® SIL G/UV₂₅₄ 0.20 mm layer plates from Machery-Nagel or on aluminum sheets with Merck silica gel (60 F₂₅₄). TLC plates were visualized using either ultraviolet light or by immersing the plate in 2% solution of ninhydrin in ethanol containing 10 drops of concentrated sulphuric acid per 100 mL followed by heating. Purification by flash column chromatography was performed using J.T Baker Silica Gel or Merck 60 Kieselgel (230 – 400 mesh). All final compounds were purified using semi-preparative RP-HPLC eluting with mixtures of acetonitrile and water (both containing 0.1% TFA). Fractions of equal purity were pooled and lyophilized. All tested compounds were analyzed by RP-HPLC and found to be of >95% purity (UV 220 nm).

(9*H*-Fluoren-9-yl)methyl (S)-(1-((2-(naphthalen-2-yl)ethyl)amino)-1-oxo-5-(3-((2,2,4,6,7-pentamethyl-2,3-dihydrobenzofuran-5-yl)sulfonyl)guanidino)pentan-2-yl)carbamate (**16**)

HBTU (0.945 g, 2.4 mmol) and DIPEA (0.66 mL, 3.7 mmol) were added to a stirred solution of Fmoc-Arg(Pbf)-OH (0.809 g, 1.2 mmol) in dry DMF (3 mL) under an argon atmosphere. The mixture was stirred at room temperature for 30 min. before a solution of 2-(naphthalen-2-yl)ethan-1-amine hydrochloride (0.518 g, 2.49 mmol) in DMF (2 mL) was added dropwise to the reaction mixture, and stirring continued for 20 h. The solvent was evaporated and the residue was partitioned between EtOAc (20 mL) and distilled water (10 mL). The organic phase was

1
2
3 washed two times with 10 mL portions of water, 20 mL of a 5% aqueous solution of KHCO₃ and
4
5 20 mL of a saturated aqueous NaCl solution, dried over MgSO₄, filtered and evaporated. The
6
7 crude product was purified by flash chromatography on silica gel (EtOAc/hexane; gradient 1:1 to
8
9 9:1) to give the title compound as a white solid (0.706 g, 67%). R_f (EtOAc/hexane 9:1) = 0.23;

2
3 HATU (0.590 g, 1.5 mmol) and DIPEA (0.41 mL, 2.3 mmol) were added to a stirring solution
4 of 5-((*tert*-butoxycarbonyl)amino)pentanoic acid (0.338 g, 1.54 mmol) in dry DMF (3 mL) under
5 an argon atmosphere. The mixture was stirred at room temperature for 30 min before a solution
6 of the crude product from the previous step (0.451 g, 0.78 mmol) in DMF (1.5 mL) was added
7 drop wise to the reaction mixture, and stirring continued for 24h. The reaction mixture was
8 partitioned between EtOAc (30 mL) and distilled H₂O (20 mL). The aqueous layer was extracted
9 with two portions of EtOAc (15 mL) and the combined organic layer washed with 15 mL of a
10 10% aqueous citric acid solution, 15 mL of a 5% aqueous KHCO₃ solution, and 15 mL of
11 saturated aqueous NaCl solution, and dried over MgSO₄. Removal of the drying agent by
12 filtration and removal of the solvent under reduced pressure gave the crude product (0.520 g).
13 Purification by flash chromatography (EtOAc/hexane; gradient 1:1 to pure EtOAc, followed by
14 EtOAc/MeOH; gradient 9:1 to 8:2) afforded 17 as colorless foam (0.358 g) which was judged to
15 be of sufficient purity for the next step. HRMS (ESI): *m/z* [M + H]⁺ calcd for C₄₁H₅₉N₆O₇S:

To a stirring solution of the crude primary amine (0.403 g, 0.61 mmol) in DMF (3 mL) was added 1*H*-pyrazole-1-carboxamide hydrochloride (0.453 g, 3 mmol) and DIPEA (0.53 mL, 3.1 mmol) and the resulting mixture was stirred under nitrogen atmosphere for 48 h. The reaction was monitored using analytical RP-HPLC. After the solvent had been evaporated, the residue was precipitated by addition of cold diethyl ether, washed with ether, purified by preparative RP-HPLC, and lyophilized (0.129 g, 21% over four steps). ¹H NMR (400 MHz, MeOD): δ = 7.59 – 7.51 (m, 3H), 7.42 (s, 1H), 7.24 – 7.10 (m, 3H), 4.01 (dd, *J* = 8.3, 5.7, 1H), 3.39 – 3.23 (m, 2H), 2.90 (t, *J* = 6.7, 2H), 2.80 (m, 2H), 2.73 (t, *J* = 7.0, 2H), 2.00 (t, *J* = 7.0, 2H), 1.51 – 1.09 (m, 8H); ¹³C NMR (101 MHz, MeOD): δ = 175.9, 174.3, 158.8, 158.8, 138.0, 135.2, 133.9, 129.3, 128.8, 128.7, 128.5, 128.5, 127.2, 126.6, 54.7, 42.2, 42.0, 41.8, 36.7, 36.1, 30.4, 29.5, 26.4, 23.8; HRMS (ESI): *m/z* [M + H]⁺ calcd for C₂₄H₃₆N₈O₂: 469.3034; found: 469.3033.

Ac-D-Arg¹-Arg²-2-Nal³-NH₂ (**4**)

Rink amide MBHA resin (0.28 g, 0.157 mmol) was swollen in DMF (5 mL) for 1h and then it was washed with DMF (5 x 5 mL). Fmoc-deprotection was done by treating the resin with a 20% piperidine in DMF (3 x 5 min, 10 mL) and subsequently washing with DMF (5 x 5 mL). Coupling of each amino acid included the addition of a solution of the Fmoc-protected amino acid (0.63 mmol), HOBt hydrate (0.085 g, 0.63 mmol), HBTU (0.233 g, 0.61 mmol), and DIPEA (0.22 mL, 1.26 mmol) in DMF (5 mL) to the resin. The completeness of each coupling was verified by the Kaiser test.²⁹ After the last coupling and Fmoc-deprotection, the resin was washed with DMF and allowed to dry. The free amino terminal of the resin was then acetylated by treating the resin with a mixture of Ac₂O, DIPEA and DMF (1:1:8, 20 mL) for 30 min. The resin was then washed with DMF followed by CH₂Cl₂, and left to air-dry. *Cleavage*. The dried resin

1
2
3 was treated with a cleavage mixture of TFA, TIS and H₂O (95:2.5:2.5, 15 mL) for 3h. The resin
4 was removed by filtration and the filtrate was evaporated to dryness under reduced pressure. The
5 crude product was purified by RP-HPLC and lyophilized. The title compound was isolated as a
6 white fluffy powder (28 mg, 22%). ¹H NMR (400 MHz, MeOD) δ = 7.82 – 7.75 (m, 3H), 7.70
7 (s, 1H), 7.47 – 7.37 (m, 3H), 4.79 – 4.67 (m, 1H), 4.31 – 4.13 (m, 2H), 3.36 – 3.29 (m, 1H), 3.09

36 Methyl (*N,N*-bis(*tert*-butoxycarbonyl)carbamimidoyl)glycinate (**19**)²⁶
37

38 To a slurry of glycine methyl ester hydrochloride (1.110 g, 8.84 mmol) in DMF (30.5 mL) was
39 added *N,N*-di-Boc-1*H*-pyrazole-1-carboximidine (1.025 g, 3.304 mmol) and DIPEA (1.15 mL,
40 6.302 mmol). Glycine methyl ester hydrochloride dissolved completely after *N,N*-di-Boc-1*H*-
41 pyrazole-1-carboximidine was added. The mixture was stirred overnight (14 h) at room
42 temperature and turned into a yellow slurry. The reaction mixture was partitioned between
43 EtOAc (25 mL) and distilled water (20 mL). The aqueous layer was further extracted three times
44 with EtOAc (25 mL), before the combined organic layers were dried over anhydrous MgSO₄ and
45 EtOAc evaporated under reduced pressure to give the crude product as a light yellow solid (1.4

9
10 triphenyl-2-oxa-12-thia-5,8-diazatridecan-10-yl)carbamate (**24**)

11
12 Et₂NH (1.47 mL) was added to a solution of the Fmoc-protected amine **23** (0.261 g, 0.29
13
14 mmol) in CH₂Cl₂ (3 mL) at room temperature. TLC monitoring showed no sign of the starting
15
16 material after one hour, but the reaction stirred for an additional hour. The solvent was removed
17
18 under reduced pressure, which gave a light yellow foam. The crude product (0.230 g) was used
19
20 directly in the next step.

21
22 To a solution of crude Fmoc-deprotected **23** (0.29 mmol) in CH₂Cl₂ (2 mL), were added
23
24 Fmoc-Cys(Trt)-OH (0.183 g, 0.31 mmol), HATU (0.112 g, 0.30 mmol) and DIPEA (0.140 mL,
25
26 0.80 mmol), resulting to a yellow reaction mixture allowed to stir in 22 hours at room
27
28 temperature. After evaporation of the solvent, the residue was partitioned between EtOAc (15
29
30 mL) and distilled water (50 mL). The aqueous layer was extracted with two portions of EtOAc
31
32 (15 mL), and the combined organic layer was washed with a 1M aqueous solution of KHSO₄ (30
33
34 mL), distilled water (30 mL), a saturated aqueous solution of NaHCO₃ (30 mL), a saturated
35
36 aqueous solution of NaCl (30 mL) and dried over anhydrous MgSO₄. Removal of the solvent
37
38 under reduced pressure gave the crude product as an orange colored foam (0.419 g). Purification
39
40 by flash column chromatography (EtOAc/hexanes, 8:2) gave **24** as a colorless foam (0.194 g, 49
41
42 % over 2 steps). ¹H NMR showed that the product retained EtOAc, and the yield is adjusted
43
44 accordingly. R_f (EtOAc/hexane, 8:2) = 0.16; ¹H NMR and ¹³C NMR gave no useful information
45

oxo-4-((tritylthio)methyl)pentyl)carbamate (**34**)

Et_2HN (1.9 mL, 18.0 mmol) was added to a stirring solution of **23** (0.334 g, 3.8 mmol) in CH_2Cl_2 (3.9 mL) at r.t. The reaction was monitored by TLC and deemed complete after 3 h. The mixture was evaporated until dryness to give the crude product (0.344 g), which was used directly in the following step.

To a stirred solution of carboxylic acid **33** (0.182 g, 0.36 mmol) in dry CH_2Cl_2 (2.1 mL), were added HBTU (0.142 g, 0.38 mmol) and DIPEA (66 μ L, 0.38 mmol) and the mixture was stirred for 30 minutes. Fmoc-protected amine **23** (0.250 g of crude product, 0.38 mmol) in dry CH_2Cl_2 (2.1 mL) was added and stirring continued for 17 h. The solvent was evaporated to give red foam, which was partitioned between EtOAc (20 mL) and water (10 mL). The organic phase was separated and washed with 10 mL portions of 5% $KHSO_4$ and saturated aqueous NaCl solutions. The organic phase was further concentrated and purified by flash chromatography on silica gel (EtOAc/hexane 3:1) to give an inseparable mixture of the two diastereoisomers of **34** as white foam (0.352 g, 85 %) The product retains EtOAc and the yield is adjusted accordingly. R_f (EtOAc/hexane, 3:1) = 0.29; HRMS (ESI): m/z $[M + H]^+$ calcd for $C_{65}H_{83}N_6O_9S_2$: 1155.5658; found: 1155.5667; HRMS (ESI): m/z $[M + Na]^+$ calcd for $C_{65}H_{82}N_6O_9S_2Na$: 1177.5477; found: 1177.5474.

1,1'-(((3*R*,6*S*,9*aS*)-8-(2-(Naphthalen-2-yl)ethyl)-4,7-dioxohexahydro-2*H*,6*H*-pyrazino[2,1-*b*][1,3]thiazine-3,6-diyl)bis(propane-3,1-diyl))diguanidine (**13**)

The diastereoisomeric mixture of linear precursor **34** (0.925 g, 0.80 mmol) was dissolved in a mixture of TFA, thioanisole and water (90:5:5, 28 mL) and the resulting mixture was stirred at room temperature for 90 min. The TFA mixture was evaporated and the crude product was precipitated by addition of cold diethyl ether. The ether was drained off and the residue was dried in vacuo to give the crude product as a reddish solid (0.422 g). The crude product (0.210 g, approx. 0.43 mmol) in dry DMF (3.5 mL) was added 1*H*-pyrazole-1-carboxamide hydrochloride (92 mg, 0.63 mmol) and DIPEA (110 μ L, 0.63 mmol), and the mixture was stirred under argon atmosphere for 72 h during which the reaction was monitored by RP-HPLC. Diethyl ether (30 mL) was then added and the mixture was cooled at 4 °C and stirred for an additional hour, resulting in the precipitation of crude product as a white solid (0.230 g). The crude was purified by preparative HPLC to give the title compound as a fluffy white solid. ^1H NMR δ = 7.82 – 7.77 (m, 3H), 7.69 (s, 1H), 7.47 – 7.40 (m, 3H), 5.14 (dd, J = 5.4, 4.6, 1H), 4.00 (dt, J = 13.6, 7.7, 1H), 3.70 (dd, J = 13.9, 4.0, 1H), 3.58 – 3.51 (m, 2H), 3.17 (t, J = 7.0, 2H), 3.10 – 3.98 (m, 5H), 2.78 – 2.73 (m, 1H), 2.58 (t, J = 12.0, 1H), 1.91 – 1.85 (m, 1H), 1.68 – 1.56 (m, 4H), 1.46 – 1.41 (m, 1H), 1.40 – 1.35 (m, 3H); ^{13}C NMR δ = 173.8, 169.4, 158.7, 158.5, 137.3, 135.0, 133.8, 129.3, 128.7, 128.51, 128.49, 128.45, 127.2, 126.7, 56.6, 52.9, 50.9 (HSQC), 49.3 (HSQC), 43.8, 42.4, 41.6, 34.4, 30.2, 28.9, 28.6, 27.5, 26.2; HRMS (ESI): m/z [M + H] $^+$ calcd for $\text{C}_{27}\text{H}_{39}\text{N}_8\text{O}_2\text{S}$: 539.2911; found: 539.2906.

1,1'-(((3*S*,6*S*,9*aR*)-8-(2-(Naphthalen-2-yl)ethyl)-4,7-dioxohexahydro-2*H*,6*H*-pyrazino[2,1-*b*][1,3]thiazine-3,6-diyl)bis(propane-3,1-diyl))diguanidine (**14**)

Biological Studies. *Transfections and tissue culture.* COS-7 cells were grown in Dulbecco's modified Eagle's medium (DMEM) with Glutamax (Invitrogen, UK) supplemented with 10% fetal bovine serum (FBS), 180 units/ml penicillin and 45 $\mu\text{g}/\text{ml}$ streptomycin (PenStrep) at 37 °C in a 10% $\text{CO}_2/90\%$ humidified atmosphere. Transfection of cells was carried out by the calcium phosphate precipitation method.^{30, 31} Briefly, plasmid DNA (20 μg of receptor cDNA and 30 μg of the chimeric $\text{G}\alpha_i$ to $\text{G}\alpha_q$ signal-converting G protein $\text{G}\alpha_{qi4\text{myr}}$) were mixed with TE-buffer (10 mM Tris-HCl, 2 mM Na_2EDTA , pH 7.5) and 30 μl calcium chloride (2 M) to a total volume of 480 μl , and then added to the same amount of HEPES buffered saline (280 mM NaCl, 50 mM HEPES, 1.5 mM Na_2HPO_4 , pH 7.2). Precipitation was allowed for 45 min at room temperature, after which the precipitate together with 300 μl chloroquine (2 mg/ml) in 10 ml culture media was added to the 6×10^6 COS-7 cells seeded the day before. Transfection was stopped after 5 h by replacing media, and cells were incubated overnight.

Functional assay. The potency was measured using a scintillation proximity-based inositol-phosphate accumulation assay (SPA-IP).³² In brief, one day after transfection COS-7 cells (0.35×10^5 cells/well) were incubated for 24 h with [³H]-myo-inositol (5 μ l/ml, 2 μ Ci/ml) in 0.1 ml of growth medium per well in a 96-well plate. The following day, cells were washed twice in PBS and were incubated in 0.1 ml of Hank's balanced salt solution (Invitrogen, U.K.) supplemented with 10 mM LiCl at 37 °C in the presence of various concentrations of ligands for 90 min. Cells were extracted by addition of 50 μ l of 10 mM formic acid to each well, followed by incubation on ice for 30–60 min. The [³H]inositol-phosphates in the formic acid cell lysates were quantified by Ysi-poly-D-Lys coated SPA beads. Briefly, 35 μ l of cell extract was mixed with 80 μ l of a SPA bead suspension (12.5 μ g/ μ l in H₂O) in a PicoPlate-96 white plate. Plates were sealed, agitated for at least 30 min and centrifuged (5 min, 1500 rpm). SPA beads were allowed to settle and react with the extract for 8 h before radioactivity was determined using a Packard Top Count NXT™ scintillation counter (PerkinElmer, MA, USA). All determinations were made in duplicate. This readout has earlier been used effectively for CXCR4 and other chemokine receptors.^{13, 33}

SUPPORTING INFORMATION

Design, Synthesis, and Biological Evaluation of Scaffold-Based Tripeptidomimetic Antagonists for CXC Chemokine Receptor 4 (CXCR4)

Zack G. Zachariassen,^a Stefanie Thiele,^b Erik A. Berg,^c Pernille Rasmussen,^c Torgils Fossen,^c Mette M. Rosenkilde,^b Jon Våbenø,^{*,a} Bengt Erik Haug^{*,c}

^aDepartment of Pharmacy, Faculty of Health Sciences, UiT The Arctic University of Norway, Breivika, NO-9037 Tromsø, Norway.
