24 **Abstract**

25 The RAR-related orphan receptors (RORs) are members of the nuclear receptor family of intracellular
26 transcription factors. In this study, we examined the regulatory properties of ROR α (CsROR α) and ROR γ
27 (CsROR γ) in tongue sole (*Cynoglossus semilaevis*). CsROR α and CsROR γ expression was detected in
28 major lymphoid organs and altered to significant extents after bacterial and viral infection. CsROR α
29 enhanced the activities of CsIL-17C, CsIL-17D, and CsIL-17F promoters, which contain CsROR α and
30 CsROR γ binding sites. CsROR γ also upregulated the promoter activities of CsIL-17D and CsIL-17F but
31 not CsIL-17C. CsROR α and CsROR γ proteins were detected in the nucleus, and overexpression of
32 CsROR α in tongue sole significantly increased the expression of CsIL-17C, CsIL-17D, and CsIL-17F,
33 whereas overexpression of CsROR γ significantly increased the expression of CsIL-17C and CsIL-17F, but
34 no CsIL-17D,. These results indicate that ROR α and ROR γ in teleost regulate the expression of IL-17
35 members in different manners.

36

37 **Key words:** ROR α ; ROR γ ; IL-17; promoter activity; *Cynoglossus semilaevis*

38

39

40 **1. Introduction**

41

42 The RAR-related orphan receptors (RORs) are members of the nuclear receptor family of intracellular
43 transcription factors (Giguère et al., 1994; Hirose et al., 1994). There are three known forms of ROR:
44 ROR α , β , and γ , each is encoded by a separate gene (*RORA*, *RORB*, and *RORC* respectively). ROR α is
45 expressed in a variety of cell types and is involved in regulation of different inflammatory responses and
46 lymphocyte development (Dussault et al., 1998). ROR γ and its spliceosome ROR γ t differ in their
47 N-terminal sequences encoded by alternative 5' exons within the *RORC* locus (Eberl et al., 2003); they are
48 the key transcription factors that orchestrate the differentiation of T-helper (Th) 17-cell lineage. Recently, it
49 is reported that the closely related ROR α , ROR γ and ROR γ t work in concert to regulate the expression of
50 IL-17A and IL-17F, and that perturbation of these transcription factors could be a viable strategy for
51 treating autoimmune pathologies linked to Th17 effector function in mammals. (Yang et al., 2008; Ruan et
52 al., 2011).

53 In the immune system, naive CD4⁺ T cells can be differentiated into Th1/Th2/Th17/Treg cells upon
54 interaction with antigen presenting cells (APCs) depending on the local cytokine milieu. The differentiation
55 requires the precise action of lineage-determining transcription factors T-box expressed in T cells (T-bet),
56 GATA binding protein 3 (GATA-3), RORs (ROR α , ROR γ and ROR γ t), and forkhead box P3 (Foxp3)
57 (Martins et al., 2005; Hwang et al., 2005; Schulz et al., 2008; Zhou et al., 2008). Th1 cells may secrete
58 effector cytokines IL-12 and IFN- γ ; Th2 cells secrete IL-4, IL-5 and IL-13; Th17 cells secrete IL-17A and
59 IL-17F; Treg cells secrete IL-10 and TGF- β (Bevan et al., 2004; Harrington et al., 2005; Steinman et al.,
60 2007; Stockinger et al., 2007; Zhu et al., 2008; Swain et al., 2012). In teleosts, ROR α , ROR γ , T-bet,

61 GATA-3, and the cytokines related to Th-cells have been identified in some species (Flores et al., 2007;
62 Castro et al., 2011; Du et al., 2012; Monte et al., 2012; Zhu et al., 2012). However, unlike mammals, little
63 is known about CD4⁺ T-cell diversity and the nature of the initial signals that determine the T-cell response
64 pattern in teleosts.

65 The IL-17 family is a subset of cytokines consisting of IL-17A (CTLA8), IL-17B, IL-17C, IL-17D,
66 IL-17E (IL-25), and IL-17F (Gu et al., 2013). In teleost, IL-17 members have been identified in several fish
67 species and are reported to play crucial roles in host defense against microbial organisms (Gunimaladevi et
68 al., 2006; Wang et al., 2014; Korenaga et al., 2010; Kono et al., 2011). It has been reported that ROR α and
69 ROR γ regulate the expression of IL-17A and IL-17F in mammals (Yang et al., 2008), yet no reports on
70 lower vertebrates have been documented. Moreover, the effect of ROR α and ROR γ on the expression of
71 other IL-17 family members also remains unknown in teleost species.

72 Half-smooth tongue sole *Cynoglossus semilaevis* is an economically favorable teleost species farmed
73 in China. Genomic sequencing has revealed the existence of ROR α (CsROR α), ROR γ (CsROR γ) genes as
74 well as three IL-17 members (CsIL-17C, CsIL-17D, and CsIL-17F) in this species (Chen et al., 2014). In
75 this study, we examined the structure and regulatory property of CsROR α and CsROR γ . In addition, the
76 effect of CsROR α and CsROR γ on the expression of CsIL-17C, CsIL-17D, and CsIL-17F was also
77 analyzed.

78

79 **2. Materials and methods**

80

81 **2.1 Fish**

82

83 Half-smooth tongue sole were purchased from a commercial fish farm in Shandong Province, China
84 and were maintained at 20°C in aerated seawater. Fish were acclimatized in the laboratory for two weeks
85 before the experimental started. Six fish were randomly sampled for the examination of the presence of
86 bacteria and megalocytivirus in blood, liver, kidney, and spleen as reported previously (Li et al., 2015a). No
87 bacteria or virus were detected from the examined fish. Before tissue collection, fish were euthanized with
88 an overdose of tricaine methanesulfonate (Sigma, St. Louis, MO, USA) as reported previously (Zhang et al.,
89 2015).

90

91 *2.2. Sequence analysis*

92

93 The cDNA and amino acid sequences of tongue sole ROR α and ROR γ (GenBank accession numbers.
94 XP_008310012.1 and XP_008321277.1) were analyzed using the BLAST program at the National Center
95 for Biotechnology Information (NCBI), the Expert Protein Analysis System, the ExPASy Molecular
96 Biology server (<http://us.expasy.org>) and Pfamp (Combet et al., 2000). Domain search was performed with
97 the simple modular architecture research tool (SMART) version 4.0 and the conserved domain search
98 program of NCBI. Amino acid identity and similarity were calculated with the Matrix Global Alignment
99 Tool (MatGAT) program v 2.0 (Campanella et al., 2003) using default parameters. A multiple sequence
100 alignment was created using CLUSTALW, and MEGA version 4.1 (Tamura et al., 2007) was used to assess
101 the similarities among the aligned sequences. A phylogenetic tree based was constructed using the
102 neighbor-joining (NJ) algorithm, and the reliability of the branching was tested using bootstrap
103 re-samplings with 1,000 pseudo-replicates. Identification of transcription factor-binding motifs was
104 performed with TRANSFAC (Biobase International) (Heinemeyer et al., 1998) and MatInspector version

105 6.2 (Cartharius et al., 2005).

106

107 ***2.3 Quantitative real time reverse transcription-PCR (qRT-PCR) analysis of CsROR α and CsROR γ***

108 ***expression under normal physiological conditions***

109

110 Spleen, heart, gill, brain, kidney, liver, muscle, and gut were obtained aseptically from five tongue sole
111 (average 14.3 g) and used for total RNA extraction with the RNAPrep Tissue Kit (Omega Bio-Tek,
112 Norcross, GA USA). One microgram of total RNA was used for cDNA synthesis with the Superscript II
113 reverse transcriptase (Invitrogen, Carlsbad, CA, USA). qRT-PCR was performed using the primers
114 CsROR α RTF/CsROR α RTR, CsROR γ RTF/CsROR γ RTR (Table 1) and carried out in an Eppendorf
115 Mastercycler (Eppendorf, Hamburg, Germany) using the SYBR ExScript qRT-PCR Kit (Takara, Dalian,
116 China) as described previously (Zheng and sun, 2011). Melting curve analysis of amplification products
117 was performed at the end of each PCR to confirm that only one PCR product was amplified and detected.
118 The expression levels of CsROR α and CsROR γ were analyzed using comparative threshold cycle method
119 ($2^{-\Delta\Delta CT}$) with ACTB as the control. All data are given in terms of mRNA levels relative to that of beta actin
120 (ACTB) as reported previously (Long et al., 2014) and expressed as means plus or minus standard errors of
121 the means (SEM). The assay was performed three times.

122

123 ***2.4 qRT-PCR analysis of gene expression during pathogen infection***

124

125 Bacterial infection was performed as reported previously (Dang et al., 2011). The fish bacterial
126 pathogen *Vibrio harveyi* (Sun et al., 2009) was cultured in Luria-Bertani broth (LB) medium at 28°C to an

127 OD₆₀₀ of 0.8. The cells were washed with PBS and re-suspended in PBS to yield 1×10^6 colony forming
128 units (CFU)/ml. The fish viral pathogen megalocytivirus RBIV-C1 (Zhang et al., 2014a) was suspended in
129 PBS to 5×10^4 copies/ml. Tongue sole were divided randomly into three groups and injected
130 intraperitoneally (i.p.) with 100 μ l *V. harveyi*, megalocytivirus, or PBS. Fish (five at each time point) were
131 euthanized at 6 h, 12 h, 24 h, and 48 h post-bacterial infection and at 1 d, 3 d, 5 d, and 7 d post-viral
132 infection. Tissues were collected under aseptic conditions. Total RNA extraction, cDNA synthesis, and
133 qRT-PCR were performed as described above. 60S ribosomal protein L18a (for spleen) and ACTB (for
134 kidney) were used as the internal controls for bacterial infection, and ACTB (for both spleen and kidney)
135 was used as the internal control for viral infection (Long et al., 2014). The assay was performed three
136 times.

137

138 **2.5 Plasmid construction**

139

140 To construct pCsROR α -RFP and pCsROR γ -RFP, which express CsROR α -TagRFP and
141 CsROR γ -TagRFP fusion proteins respectively, the coding sequences of CsROR α and CsROR γ were
142 amplified with primers CsRORaEcoRIF/CsRORaEcoRIR and CsRORrHindIIIF/CsRORrHindIIIR (Table
143 1), respectively, and the PCR products were inserted into pTagRFP-N (Evrogen, Moscow, Russia) at the
144 EcoRI or HindIII site. To construct pCsROR α and pCsROR γ , which express His-tagged CsROR α and
145 CsROR γ respectively, the coding sequences of CsROR α and CsROR γ were amplified with primers
146 CsRORaF1/CsRORaR1 and CsRORrF1/CsRORrR1 respectively, and the PCR products were inserted into
147 pCN3 (Li et al., 2015b) at the EcoRV site.

148 Genomic DNA was isolated from tongue sole spleen with the TIANNamp Marine Animals DNA kit

149 (Tiangen, Beijing, China). About 1200 bp of the 5' flanking region sequences of the CsIL-17C, CsIL-17D
150 and CsIL-17F genes were obtained from the genomic DNA by PCR using the primers
151 CsIL17CproF/CsIL17CproR, CsIL17DproF/CsIL17DproR, and CsIL17FproF/CsIL17FproR (Table 1),
152 respectively, and the PCR products were inserted into pMetLuc-2 (Clontech, Mountain View, CA, USA) at
153 the HindIII site. All plasmid DNA constructs were isolated using Endo-Free plasmid maxi kit (Omega
154 Bio-Tek, Norcross, GA, USA).

155

156 ***2.6 Cell culture, transfection and reporter activity assay***

157

158 The cell line FG-9307 was derived from the gill tissue of flounder *Paralichthys olivaceus*. The cells
159 were maintained in Eagle's minimal essential medium (MEM) (Gibco, Grand Island, USA) supplemented
160 with 10% fetal bovine serum (FBS) (Gibco) at 22°C. Transfection was performed as reported previously
161 (Zhang et al., 2014b). Briefly, FG cells were distributed into 24-well culture plates (2×10^5 cells/well) in
162 MEM medium without FBS. Transfection of the cells with pCsROR α -RFP, pCsROR γ -RFP and
163 pTagRFP-N was performed with Lipofectamine LTX and PLUSTM (Invitrogen, Carlsbad, CA, USA)
164 according to the instructions given by the manufacturer. After transfection for 24 h, the medium was
165 removed and replaced with new medium containing 500 ng/ml lipopolysaccharides (LPS) (Sigma, St Louis,
166 MO, USA). After incubation at 22°C for 6 h, the cells were fixed with 4% formaldehyde for 0.5 h, and 4,
167 6-diamino-2-phenyl indole (DAPI) (Invitrogen) was used for nucleic acid staining according to
168 manufacturer's instructions. The cells were observed with fluorescence microscope (Carl Zeiss Imager A2,
169 Jena, Germany).

170 For reporter activity assay, the FG cells were re-suspended in MEM medium and seeded in 24-well

171 culture plates (2×10^5 cells/well). Transfection of the cells with different proportions of pCsROR α ,
172 pCsROR γ , pCN3 and reporter vectors was performed with Lipofectamine LTX and PLUSTM according to
173 manufacturer's instructions. The pSEAP2 (Clontech, Mountain View, CA, USA) control vector for
174 normalizing transfection efficiency was included in all assays. After transfection for 48 h, the culture
175 mediums of the transfectants were analyzed for luciferase activity and SEAP activity using the Luciferase
176 Assay Kit (Clontech) and the Great EscAPeTM SEAP Chemiluminescence Detection Kit (Clontech),
177 respectively.

178

179

180 ***2.7 Overexpression of CsROR α and CsROR γ in vivo***

181

182 Overexpression of CsROR α and CsROR γ *in vivo* was performed as reported previously (Zhou et al.,
183 2014). Briefly, pCsROR α , pCsROR γ , and the control plasmid pCN3 were diluted in PBS to 200 μ g/ml.
184 Tongue sole were divided randomly into four groups and injected intramuscularly with 100 μ l of pCsROR α ,
185 pCsROR γ , pCN3, or PBS. Tissues were taken from 5 fish at 5 days post-plasmid administration and used
186 for examination of the presence of plasmids and the mRNA expression of *ROR α* , *ROR γ* , *IL-17C*, *IL-17D*
187 *IL-17F*, *T-bet* and *GATA-3* (GenBank accession numbers: XP_008310012.1, XP_008321277.1,
188 XP_008309677.1, XP_008326667.1, XP_008335392.1, XP_008312713.1, and XP_008314324.1
189 respectively). PCR detection of pCsROR α , pCsROR γ , and pCN3 was performed with the primers pF1/pR1
190 (Table 1). To examine expression of plasmid-derived *CsROR α* and *CsROR γ* , *IL-17C*, *IL-17D* *IL-17F*, *T-bet*
191 and *GATA-3*, total RNA was extracted from the tissues as described above and used for RT-PCR with the
192 primer pairs shown in Table 1. The experiment was repeated three times.

193

194 *2.8. Statistical analysis*

195

196 All statistical analyses were performed with SPSS 17.0 software (SPSS Inc., Chicago, IL, USA). Data
197 were analyzed with analysis of variance (ANOVA), and statistical significance was defined as $P < 0.05$.

198

199 **3. Results**

200

201 *3.1 Nucleotide and deduced amino acid sequences of CsROR α and CsROR γ*

202

203 CsROR α and CsROR γ are composed of 468 amino acids (molecular mass of 53.0 kDa) and 469 amino
204 acids (54.0 kDa), respectively. Secondary structure analysis using SOPMA software indicated that CsROR α
205 and CsROR γ were comprised of α -helixes (47.44% and 44.56%) and random coils (32.26% and 29.0%)
206 connected by extended strands (13.03% and 17.91%) and β -turns (7.26% and 8.53%). According to
207 BLAST search, CsROR α and CsROR γ share 91-99.6% and 45.3-72.4%, respectively, overall sequence
208 identities with the equivalent genes of other teleost species and humans (Fig. 1A and Fig. 2A). Sequence
209 alignment revealed the presence of a conserved ZnF_C4 (C4 zinc finger in nuclear hormone receptors) and
210 HOLI (Ligand binding domain of hormones) domains in CsROR α and CsROR γ (Fig. 1B and Fig. 2B). A
211 phylogenetic tree based on multiple alignments of the ROR family genes from various vertebrates showed
212 that the lineage sorting of the clusters corresponded to the sequence identities of the respective genes of
213 ROR family. Three distinct branches were generated, namely ROR α , ROR β , and ROR γ . CsROR α and
214 CsROR γ fell into the ROR α and ROR γ clades, respectively (Fig. 3).

215

216 **3.2 Distribution of *CsRORα* and *CsRORγ* in fish tissues under normal conditions**

217

218 As shown in Fig. 4, the *CsRORα* and *CsRORγ* genes were expressed in all the tissues analyzed.
219 *CsRORα* was expressed, in increasing order, in the spleen, kidney, blood, liver, gill, heart, intestine, muscle,
220 and brain (Fig. 4A), while *CsRORγ* was expressed, in increasing order, in the spleen, blood, liver, muscle,
221 brain, intestine, kidney, gill, and heart (Fig. 4B).

222

223 **3.3 Regulation of the expression of *CsRORα* and *CsRORγ* by bacterial and viral infection**

224

225 The expression levels of *CsRORα* and *CsRORγ* following bacterial and megalocytivirus infection were
226 examined in the spleen and kidney. When the fish were infected with the bacterial pathogen *V. harveyi*, the
227 mRNA transcript of *CsRORα* was significantly upregulated in spleen and the maximum fold increase
228 (5.27-fold) occurred at 12 h (Fig. 5A). In kidney, *CsRORα* expression was significantly increased at 12 h
229 and 24 h post-infection, with a maximum of 7.87-fold increase at 24 h (Fig. 5B). The mRNA level of
230 *CsRORγ* was significantly increased in spleen (7.00-fold) and kidney (17.29-fold) at 6 h post-infection (Fig.
231 5E and Fig. 5F). When the fish were infected with the viral pathogen megalocytivirus, the *CsRORα*
232 expression was significantly upregulated in spleen (3.66-fold) and kidney (3.29-fold) at 7 d (Fig. 5C and
233 Fig. 5D). For *CsRORγ*, the mRNA transcript in spleen was significantly decreased at 3 d (0.17-fold) and 5 d
234 (0.12-fold) post-infection compared to the control (Fig. 5G); the same trend was observed in the kidney at 3
235 d (0.43-fold) and 7d (0.25-fold) post-infection (Fig. 5H).

236

237 ***3.4 Intracellular localization of CsROR α and CsROR γ***

238

239 To examine the subcellular localization of CsROR α and CsROR γ , FG cells were transfected with
240 pCsROR α -RFP and pCsROR γ -RFP, which express CsROR α and CsROR γ respectively, fused to red
241 fluorescent protein (RFP). Microscopy showed that in the transfectants, CsROR α and CsROR γ were
242 observed to overlap with the nuclei (blue), whereas in the cells transfected with the control vector
243 (pTagRFP-N), RFP was found to be expressed evenly in the cytoplasm (Fig. 6).

244

245 ***3.5 Effect of CsROR α and CsROR γ on the promoter activity of IL-17 cytokines***

246

247 In a previous study, the CsIL-17C, CsIL-17D and CsIL-17F promoter reporter plasmids
248 pLucCsIL-17C, pLucCsIL-17D, and pLucCsIL-17F, respectively, were created (Chi et al., manuscript
249 submitted), in which the promoter activities were reflected by the activities of the luciferase reporter. The
250 promoters contain ~1.2 kb 5'-flanking regions (5'-FRs) of CsIL-17C, CsIL-17D and CsIL-17F, which
251 exhibit putative ROR α and ROR γ binding sites (ROREs) (Fig. S1). In the current study, we examined the
252 potential effect of CsROR α and CsROR γ on the activity of the CsIL-17C, CsIL-17D and CsIL-17F
253 promoters. For this purpose, FG cells were transfected with pCsROR α and pCsROR γ plus pLucCsIL-17C,
254 pLucCsIL-17D, or pLucCsIL-17F, and the luciferase activities were determined. The results showed that in
255 pLucCsIL-17C transfectants, luciferase activity was significantly increased in the presence of pCsROR α
256 (3.19-fold), but not in the presence of pCsROR γ (Fig. 7A). In pLucCsIL-17D transfectants, luciferase
257 activity was significantly increased in the presence of pCsROR α and pCsROR γ (3.64- and 2.58-fold
258 respectively) (Fig. 7B). In the pLucCsIL-17F transfectants, luciferase activity was also significantly

259 increased in the presence of pCsROR α and pCsROR γ (2.85- and 3.31-fold respectively) (Fig. 7C).

260

261 **3.6 Biological effect of *CsROR α* and *CsROR γ* in tongue sole**

262

263 In order to examine the *in vivo* biological effect of the CsROR α and CsROR γ , tongue sole were
264 administered with pCsROR α , pCsROR γ , or the control vector pCN3. At 5 days post-plasmid administration,
265 the presence of the plasmids and expression of the plasmid-derived *CsROR α* and *CsROR γ* were examined
266 by PCR and RT-PCR respectively (Fig. S2). By PCR, pCsROR α , pCsROR γ , and pCN3 were all detected in
267 the muscle, spleen, and kidney. RT-PCR showed that the expression of pCsROR α - and pCsROR γ -derived
268 *CsROR α* and *CsROR γ* was found in the fish administered with pCsROR α and pCsROR γ respectively, but
269 not in the control fish (Fig. S2).

270 The expression of IL-17C, IL-17D, IL-17F, T-bet, and GATA-3 genes in the kidney of pCsROR α - and
271 pCsROR γ -administered fish was determined by qRT-PCR at 5 d post-plasmid injection. The results showed
272 that compared to fish administered with the control plasmid pCN3, fish administered with pCsROR α
273 exhibited significantly upregulated expression of IL-17C, IL-17D and IL-17F, significantly decreased
274 expression of T-bet, and no significant change in the expression of GATA-3. pCsROR γ -injected fish
275 exhibited significantly increased expression of IL-17C and IL-17F, significantly decreased expression of
276 T-bet and GATA-3, and no significant change in the expression of IL-17D (Fig. 8).

277

278 **4 Discussion**

279

280 In this report, we studied the gene structure, expression profile, and transcriptional property of

281 CsROR α and CsROR γ from tongue sole. Multiple alignment analysis revealed that CsROR α and CsROR γ
282 shared high degrees of identities with homologues of other teleost species and humans, suggesting that
283 CsROR α and CsROR γ are highly conserved among lower and higher vertebrates, which is consistent with
284 their fundamental roles in cells (Flores et al., 2007; Monte et al., 2012; Du et al., 2012). Both CsROR α and
285 CsROR γ contain ZnF_C4 and HOLI domains, the former is a small DNA-binding peptide motif that can be
286 used as modular building blocks for the construction of larger protein domains that recognize and bind to
287 specific DNA sequences (Klug et al., 1999). HOLI is a ligand-binding domain that acts in response to
288 ligand binding, causing a conformational change in the receptor to induce a response, thereby acting as a
289 molecular switch to turn on transcriptional activity (Bledsoe et al., 2004). The presence of these structural
290 features in CsROR α and CsROR γ suggests a conserved operational mechanism of ROR α and ROR γ in
291 lower and higher vertebrate species.

292 In mammals, ROR α and ROR γ exhibit distinct tissue-specific expressions. ROR α is expressed in a
293 variety of tissues, including testis, kidney, liver, and particularly brain (Becker-Andre et al., 1993; Carlberg
294 et al., 1994; Hamilton et al., 1996; Dussault et al., 1998). ROR γ has been found to be highly expressed in
295 the liver, skeletal muscle, and kidney of mammalian species (Eberl and Littman, 2003; Eberl and Littman,
296 2004; Jetten, 2004; Jetten and Joo, 2006). Similar to mammals, in tongue sole we found that the expression
297 of CsROR α and CsROR γ occurred in multiple tissues. CsROR α was highly expressed in intestine, muscle
298 and brain, while CsROR γ was highly expressed in kidney, gill, and heart. This is in consistence with the
299 reports on grass carp and zebrafish (Du et al., 2012; Monte et al., 2012). It is known that the expression of
300 ROR α and ROR γ in lymphoid organs is stimulated after bacterial infection or LPS stimulation (Du et al.,
301 2012; Monte et al., 2012). Similarly, we found that the expression of CsROR α and CsROR γ was
302 upregulated by experimental infection with the bacterial pathogen *V. harveyi*. However, after viral infection,

303 CsROR γ expression was inhibited, while CsROR α expression was enhanced. These results indicate that
304 CsROR α and CsROR γ responded differently to different types of pathogens.

305 Previous studies have shown that RORs binds to a consensus core sequence and regulates the
306 expression of IL-17 (Giguère et al., 1994; Carlberg et al., 1994; Medvedey et al., 1996; Ruan et al., 2011).
307 In Atlantic salmon, the 5' flanking region of IL-17D contains some putative ROREs (Kumari et al., 2009).
308 Likewise, we found that multiple ROREs are present in the 5'-flanking regions of the CsIL-17C, CsIL-17D
309 and CsIL-17F genes. In mammals, IL-17C promotes Th17 cell responses and autoimmune disease via the
310 IL-17 receptor E (Chang et al., 2011); IL-17F plays an important role in antitumor immunity in Th17
311 cell-dependent autoimmune disease, and the regulation of ROR α and ROR γ on IL-17F has been widely
312 reported (Ivanov et al., 2006; Yang et al., 2008). In our study, co-transcriptional activity analysis showed
313 that CsROR α increased the promoter activities of CsIL-17C, CsIL-17D and CsIL-17F, and that CsROR γ
314 also upregulated the promoter activities of CsIL-17D and CsIL-17F but had no effect on CsIL-17C
315 promoter activity. These results suggest that CsROR α and CsROR γ had different regulatory effects on
316 IL-17 members. In agreement with these observations, subcellular distribution analysis showed that in FG
317 cells transfected with pCsROR α -RFP and pCsROR γ -RFP, CsROR α and CsROR γ were detected in the
318 nucleus, suggesting that CsROR α and CsROR γ were localized in the nucleus.

319 Transcription factors play a critical role during the differentiation of Th cells that may result in Th cell
320 polarization. ROR α overexpression has been shown to reduce the frequency of IFN- γ -producing cells (Th1)
321 and IL-5-producing cells (Th2) in mice (Yang et al., 2008). ROR γ may control Th1/Th2 cytokine balance
322 during adaptive immune response, and it has been reported that IFN- γ production was markedly increased
323 in the splenocytes of ROR γ -deficient mice (Tilley et al., 2007). In our study, the expression levels of
324 IL-17C, IL-17D and IL-17F in tongue sole increased after CsROR α overexpression, which is in line with

325 the *in vitro* observation that CsROR α overexpression upregulated the promoter activities of these IL-17
326 members. Fish injected with pCsROR γ exhibited upregulation of IL-17C and IL-17F, but not IL-17D,
327 expression. These results indicate that the expressions of these three IL-17 members were regulated
328 differently by CsROR α and CsROR γ overexpression *in vivo*. In mammals, T-bet and GATA-3 are master
329 transcription factors involved in the process of Th1 and Th2 polarization respectively (Szabo et al., 2003;
330 Ansel et al., 2006). In our study, the expression of T-bet was suppressed after CsROR α and CsROR γ
331 overexpression. The expression of GATA-3 was also inhibited after CsROR γ overexpression but not after
332 CsROR α overexpression. These results indicate a certain balance of the expressions of transcription factors,
333 which could be the case if there exist in tongue sole Th1/Th2/Th17-like cells as reported in some mammals
334 (Tilley et al., 2007; Yang et al., 2008). However, functional proofs must be presented before stating that fish
335 possess mammalian-like Th cells.

336 In summary, we have compared the expression and regulatory functions of ROR α and ROR γ in tongue
337 sole. We found for the first time that teleost ROR α and ROR γ are involved in the regulation of the IL-17C,
338 IL-17D and IL-17F expression, and that the regulation patterns of ROR α and ROR γ differ in some aspects.

516 **Figure 4.** CsROR α and CsROR γ expression in fish tissues under normal physiological condition. CsROR α
517 and CsROR γ expression in the spleen, kidney, blood, liver, gill, heart, intestine, muscle, and brain of tongue

518 sole was determined by quantitative real time RT-PCR. For comparison, the expression levels of CsROR α
519 and CsROR γ in spleen (the lowest expression levels) were set as 1. Data are the means of three independent
520 experiments and shown as means \pm SEM.

521 **Figure 5.** Expression of CsROR α and CsROR γ in response to bacterial and viral infection. Tongue sole
522 were infected with *Vibrio harveyi* or megalocytivirus. The control fish were mock infected with PBS.
523 CsROR α (A to D) and CsROR γ (E to H) expression in kidney and spleen was determined by quantitative
524 real time RT-PCR at various time points. In each case, the expression level of the control fish was set as 1.
525 Data are the means of three independent experiments and shown as means \pm SEM. ** $P < 0.01$; * $P < 0.05$.

526 **Figure 6.** Subcellular localization of recombinant CsROR α and CsROR γ in FG cells. FG cells were
527 transfected with pCsROR α -RFP, pCsROR γ -RFP, or the control vector pTagRFP-N. The cells were stained
528 with DAPI and examined with a fluorescence microscope. In all cases, the right panels are merges of the
529 left and middle panels. Arrows indicate some representative transfectants. Bar = 10 μ m.

530 **Figure 7.** Effect of CsROR α and CsROR γ on CsIL-17C (A), CsIL-17D (B), and CsIL-17F (C) promoter
531 activity. FG cells were transfected with pLucCsIL-17C, pLucCsIL-17D, pLucCsIL-17F, pCsROR α ,
532 pCsROR γ , pMetLuc2, pSeap-Control, or pCN3 in different combinations and concentrations. The
533 luciferase activity of the transfectants was subsequently determined. Data are the means of three
534 independent experiments and shown as means \pm SEM. Bars labeled with different small letters are
535 significantly different ($P < 0.05$).

536 **Figure 8.** Gene expression in fish overexpressing CsROR α and CsROR γ . Tongue sole were injected with
537 pCsROR α , pCsROR γ , or the control vector pCN3, and the expression of IL-17C, IL-17D, IL-17F, T-bet,
538 and GATA-3 in kidney was determined by quantitative real time RT-PCR at 5 days post-injection. The
539 expression levels of the control fish were set as 1. Data are the means of three independent experiments and

540 shown as means \pm SEM. ** $P < 0.01$, * $P < 0.05$.

587

588 **Figure S2.** Detection of pCsROR α , pCsROR γ and pCN3 plasmids (A) and expression of *CsROR α* and
589 *CsROR γ* (B and C) in kidney. A. Tongue sole were administered with pCsROR α , pCsROR γ , pCN3, or PBS
590 (lanes 1 to 4 respectively), at 5 days post-administration DNA was extracted from kidney and used for PCR
591 with primers specific to the common backbone of pCsROR α , pCsROR γ , and pCN3. B. Tongue sole were
592 administered with pCsROR α (lane 1), pCsROR γ (lane 3), and pCN3 (lanes 2 and 4), at 5 days
593 post-administration, RNA was extracted from the kidney of the fish and used for RT-PCR with primers
594 targeting pCsROR α -derived *CsROR α* (lanes 1 and 2) and pCsROR γ -derived *CsROR γ* (lanes 3 and 4). C.
595 The samples in (B) were used for RT-PCR with primers specific to β -actin (internal reference). M, DNA
596 markers.
